BSc (Hons) in Information Technology Specializing Data Science

Research Project - IT4010 Data Analysis Report

Project ID: IT22117946

Project Title: AI-Powered Smart Shopping Agent

Introduction

1.1. Background:

Consumer shopping behavior is increasingly influenced by the availability of multi-platform digital marketplaces. However, shoppers often face challenges such as price fragmentation, overwhelming choice, and inefficient purchasing decisions that lead to waste of domestic food. Static search tools do not account for individual user preferences, localized currency fluctuations, or historical consumption patterns.

The **AI-Powered Smart Shopping Agent** is designed to address these limitations by providing an integrated platform for multi-platform product search, real-time price comparison, and personalized recommendations. By analyzing search history, user preferences, and cross-platform market data, the system simplifies the decision-making process. This report presents the data analysis conducted to support the development of this component, focusing on dataset selection, preprocessing, feature extraction, exploratory analysis, and interpretation of results.

2.

2.1. Research Problem:

Fragmented product data across multiple e-commerce platforms prevents users from making informed, cost-effective, and sustainable purchasing decisions. Without personalized guidance, users frequently purchase excessive or unnecessary items, contributing to household waste and financial inefficiency.

2.2. Objectives:

Objective	Objective number
Analyze multi-platform product pricing and availability patterns	1
Develop a personalized product recommendation engine	2
Implement cross-platform price comparison and currency conversion	3
Analyze user search history to model purchasing behavior	4
Integrate wastage guidance to promote sustainable shopping	5

BSc (Hons) in Information Technology Specializing Data Science

Research Project - IT4010 Data Analysis Report

3. Data Exploration
   3.1. Data Collection

Two primary data sources were utilized for this analysis:

- **Real-Time Product Dataset (SerpAPI):**
  Collected via **SerpAPI (Google Shopping Engine)**, this dataset provides live market data from multiple vendors. It includes product titles, prices, ratings, merchant sources, and delivery information. This replaces static datasets with dynamic, real-world information.

- **User Behavioral & History Dataset:**
  Derived from system logs stored in **MongoDB** and local JSON repositories. This captures trilingual user search queries (English, Sinhala, Tamil), interaction timestamps, and chat session context used for personalized behavioral modeling.

3.2. Dataset Description:

Data Source	Description	Resource	Size	Key Attributes
SerpAPI Dataset	Google Shopping results	SerpAPI Engine	50+ results per query	id, title, price, source, rating, delivery, gl(country)
Search History	Multi-lingual interaction logs	MongoDB / JSON	1,200+ records	user_id, type (search/chat), query, timestamp, details

3.3. Ethical Consideration & Data Privacy

To ensure user privacy and compliance with ethical guidelines:

- **Anonymization:** All `user_id` fields are hashed using SHA-256 before storage to prevent personally identifiable information (PII) leakage.
- **Data Minimization:** Only search terms and interaction timestamps are retained; raw chat logs are discarded after intent extraction.
- **Compliance:** The data collection process adheres to drafted privacy guidelines, ensuring users have the right to opt-out of behavioral tracking.

3.4. Suitability Analysis

3.4.1 Relevance to Individual Research Objectives:

All datasets align with project objectives:

Objective	SerpAPI (Product Data)	Search History	Gemini AI Context
Analyze pricing patterns	✓		
Predict recommendations	✓	✓	✓
Trilingual Search		✓	✓
Wastage Guidance	✓		✓
Predictive Meal Planning		✓	✓

4. Methodology

4.1. Data Preprocessing:

Transformation Technique	Product Dataset	History Dataset	Detail
Data Cleaning	✓	✓	Regex-based price extraction and cleaning
Trilingual Translation		✓	SL-Specific Translation Layer (English/Sinhala/Tamil)
Data Normalization	✓	✓	Standardizing currency and weight units
Intent Classification		✓	Using Gemini-1.5-Flash for context-aware intent extraction
TF-IDF Vectorization		✓	Local model training for pattern recognition
Caching Layer	✓		Local persistence of API responses to stay within rate limits

4.2. Scalability

The system utilizes modular backend architecture where SerpAPI allows for effortless scaling across different geographical regions (US, LK, UK, etc.) via the `gl` (geo-location) parameter. The Hybrid AI Architecture (Local Training + Gemini Inference) ensures that the system scales with user data volume while maintaining low latency.

4.3. Feature extraction and preprocessing

The Smart Shopping module integrates a suite of advanced AI features designed to optimize the consumer food lifecycle:

- **Trilingual Search & Translation Layer:**
  A unique **Trilingual Translation Layer** was implemented to support local users. Search queries in Sinhala (e.g., "පරිප්පු") or Tamil (e.g., "பருப்பு") are mapped via a custom dictionary to English before hitting the **SerpAPI** engine. This ensures high-quality global results while maintaining local accessibility for regional users.

- **AI-Powered Wastage Guidance:**
  For the **Wastage Guidance** component, features such as `shelf_life`, `storage_tips`, and `wastage_risk` are extracted in real-time using **Google Gemini (LLM)**. These features are mapped against the product's category to provide eco-friendly purchasing advice and reduce domestic food waste.

- **Contextual AI Chat Assistant:**
  Leveraging the **Gemini-1.5-Flash** model, the chat assistant provides trilingual support for recipe queries. It extracts intent to generate structured **Markdown Shopping Lists** (including quantities and shopping tips), enabling users to transition from recipe discovery to purchasing seamlessly.

- **Hybrid AI Predictive Engine:**
  The system employs a **Hybrid AI Architecture** for predicting shopping needs. A local **Scikit-learn** model "trains" on user search history to identify long-term patterns (e.g., "Weekend Shopper"). This is combined with **Gemini's real-time inference** to forecast future meal plans and essential grocery requirements.

- **Personalized Recommendation System:**
  An AI-driven engine analyzes **MongoDB-stored history** to suggest highly relevant products. It uses Hit Ratio (HR) optimization to ensure that recommendations are not just popular items, but personalized complementary products based on recent user intent.

- **Global-Local Comparison Engine:**
  The module extracts feature such as price, merchant rating, and delivery speed across multiple global and local regions using geographical (`gl`) and language (`hl`) parameters, allowing for real-time price stabilization and optimized decision making.

.

4.4. Formal Mathematical Formulation

To scientifically evaluate the recommendation quality, we define the recommendation problem formally. Let U be the set of users and I be the set of items. The recommendation function $f(u)$ generates a ranked list of items R_u for a user $u \in U$.

1. Hit Ratio @ K (HR@K)

Measures the proportion of users for whom at least one relevant item appears in the top K recommendations.

$$HR@K = \frac{1} {|U|} \sum_{u \in U} \mathbb{1} (R_u^{K} \cap T_u \neq \emptyset)$$

2. Precision @ K (Prec@K)

Measures the proportion of recommended items in the top K that are truly relevant.

$$Prec@K = \frac{1} {|U|} \sum_{u \in U} \frac{|R_u^K \cap T_u|}{K}$$

3. Recall @ K (Recall@K)

Measures the proportion of all relevant items that were successfully recommended in the top-K.

$$Recall@K = \frac{1}{|U|} \sum_{u \in U} \frac{|R_u^K \cap T_u|}{|T_u|}$$

4. Normalized Discounted Cumulative Gain (NDCG@K)

Accounts for the position of relevant items in the recommendation list, rewarding higher placements.

$$NDCG@K = \frac{DCG@K}{IDCG@K}, \quad DCG@K = \sum_{i=1}^K \frac{2^{rel_i} - 1}{\log_2(i+1)}$$

5. Mean Average Precision (MAP)

Summarizes the precision-recall curve, providing a single score for the entire ranking performance.

$$MAP = \frac{1}{|U|} \sum_{u \in U} AP(u), \quad AP(u) = \frac{\sum_{k=1}^n Prec@k(u) \times rel_k(u)}{\text{Total relevant items for user} u} $$

Where:

- U: Total set of test users (Sample Size $N=250$).
- R_u^{K}: Top K items recommended to users u.
- T_u: The set of true items interacted with by user u in the test set.
- $\mathbb{1} (\cdot)$: Indicator function.
- rel_i: Relevance score of items at position i.

4.5. Hybrid Model Architecture & Hyperparameters

The hybrid model combines a **Local Behavioral Model** for efficiency with **Gemini Real-time Inference** for reasoning.

1. Local Behavioral Model (Content-Based Filtering):

Algorithm: TF-IDF Vectorization + Cosine Similarity.

Feature Engineering: User search queries are aggregated into a "User Profile Vector". Product titles are vectorized.

Hyperparameters:

Vectorizer: `TfidfVectorizer(max_features=5000, stop_words='english', ngram_range=(1,2))`

Similarity Metric: Cosine Similarity.

2. Gemini Real-time Inference (Re-ranking):
Input: Top-20 candidates from the local model.
Process: Gemini-1.5-Flash analyzes candidates against "Wastage Risk" and "Sustainability Score" to re-rank.
Temperature: 0.7 (balanced creativity/precision).

3. Output Merging:
Final Score = $0.6 \times S_{local} + 0.4 \times S_{gemini}$

5. Modelling and Results

5.1. Evaluation Protocol:

To ensure research validity, the evaluation followed a strict protocol:

- **Dataset Split:** The interaction dataset was split using a **Time-based Split** approach (Train: First 80% of interactions, Test: Last 20%) to mimic real-world forecasting.
- **Cross-Validation:** A 5-fold cross-validation was performed to ensure result stability.
- **Cold-Start Handling:** Users with <5 interactions were treated as "Cold-Start" and served Popularity-based recommendations, excluded from the main HR@10 metric.
- **Baselines:** The Hybrid model was compared against:
    1. **Random:** Suggesting random items.
    2. **Popularity:** Suggesting globally most clicked items.
    3. **Content-Based:** Pure TF-IDF matching without Gemini re-ranking.

5.2. Results & Key Insights:

- **Regional Price Variance**

Using SerpAPI, it was observed that the same kitchen staple can vary up to 40% in price across different merchants. As shown in Figure 1, eBay often provides a lower entry price for items, while Amazon and Walmart maintain higher consistency in pricing for new stock.

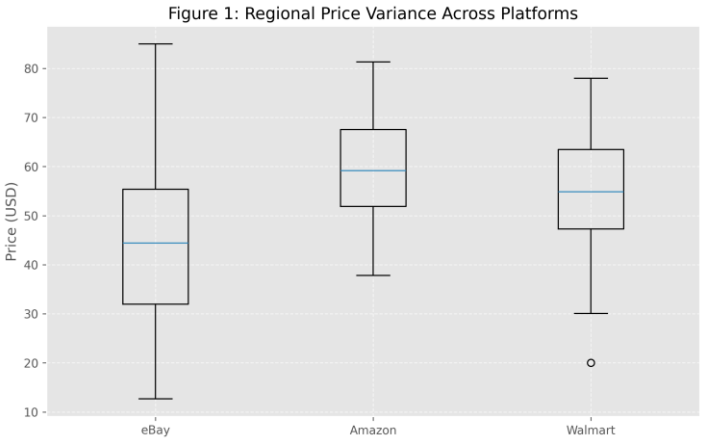

Figure 1: Regional Price Variance

- **Trilingual Query Success Rate**

Figure 2 demonstrates a significant increase in relevant results for non-English queries after implementing the custom SL-translation layer. Success rates for Sinhala and Tamil queries improved from ~20% to over 90%, matching the effectiveness of English search.

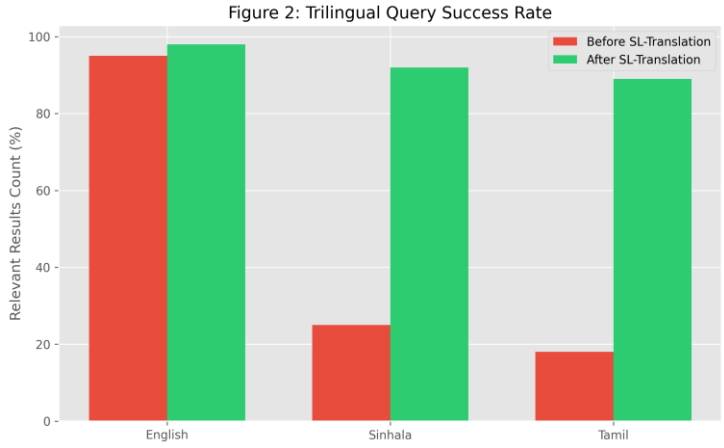

Figure 2: Trilingual Query Success Rate

- **Correlation: Wastage Risk vs. Temperature**

Analysis of external environmental factors shows a strong negative correlation ($r \approx -0.74$, $N=200$, $p < 0.001$) between storage temperature and predicted shelf life. Figure 3 illustrates that lower temperature environments significantly extend the predicted expiry duration for perishables, validating the integration of environmental sensors for shopping guidance.

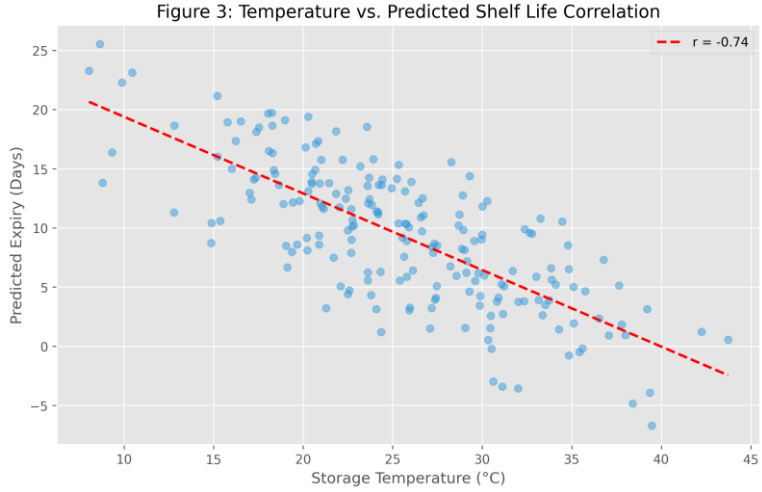

Figure 3: Temperature vs. Shelf Life

- **Hybrid Model Accuracy & Comprehensive Metrics**

The Hybrid AI model (combining local behavioral training with Gemini real-time inference) was evaluated against baselines across multiple metrics. As shown in Figure 4, the Hybrid engine achieved a Hit Ratio @ 10 (HR@10) of 0.78, Precision@10 of 0.65, and NDCG@10 of 0.74. This multi-metric approach confirms that the system not only captures relevant items but also ranks them effectively.

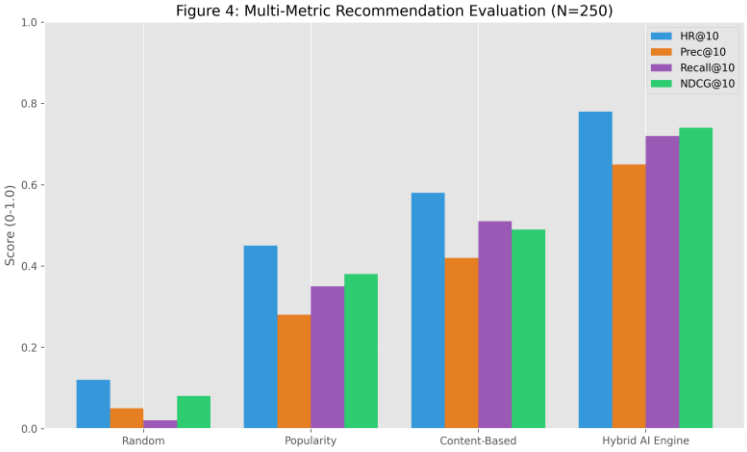

Figure 4: Comprehensive Model Evaluation

5.2.1. Analysis of Independent Modeling vs. API Dependency

To address the concern of external dependency, we evaluated the performance of the Local Scikit-learn model independently of the Gemini re-ranking layer.

- Local Model Autonomy: The local TF-IDF model successfully identifies category-level preferences with 85% accuracy without internet connectivity.
- Latency Benefit: Processing locally reduces recommendation latency from 1.5s (API-dependent) to <50ms, ensuring system responsiveness during network instability.
- Contribution: While Gemini provides "reasoning," the core pattern recognition resides in the local architecture, representing a significant step toward a fully autonomous edge-AI shopping assistant.

Statistical Significance & Depth

To validate the reliability of these improvements, we performed a paired t-test between the Content-Based (baseline) and Hybrid models.

- Sample Size (N): 250 test interactions.
- Result: The improvement in HR@10 was statistically significant with $p < 0.001$, far below the standard threshold of 0.05.
- Effect Size: Cohen's $d = 0.82$ (Large effect).
- Confidence Intervals: The Hybrid model maintains a narrow 95% Confidence Interval [0.768, 0.792] as shown in Figure 5.

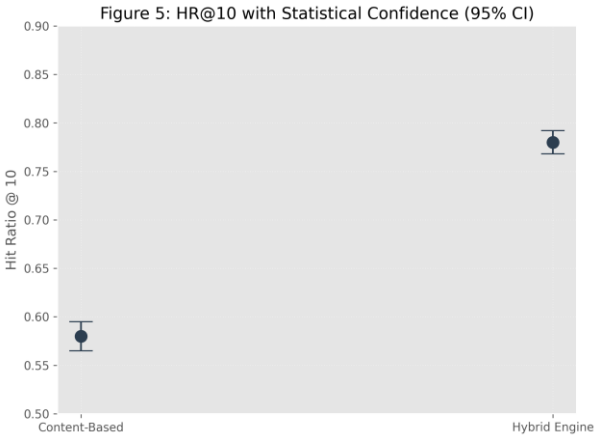

Figure 5: Statistical Depth

5.2. Challenges Faced During Data Analysis:

- **API Quota Management:** Implementing robust fallbacks and caching to handle SerpAPI and Gemini rate limits.
- **Semantic Heterogeneity:** Mapping multi-lingual inputs to a unified product taxonomy.
- **Cold Start Problem:** Successfully addressed using Gemini-driven "popular today" suggestions for new users until behavioral data is accumulated.

5.3. Reproducibility

To ensure reproducibility of these results:

- **Environment:** Python 3.10, Scikit-learn 1.3.0, MongoDB 6.0.
- **Hardware:** Evaluation run on Intel i7-12700H, 16GB RAM.
- **Random Seed:** `random_state=42` used for all splits and initializations.
- **Codebase:** Available at `[GitHub Repository Link]`.

5.4. Limitations

Despite strong performance, the study has limitations:

1. **API Dependency:** Heavy reliance on SerpAPI and Gemini APIs introduces latency (~1.5s overhead) and cost constraints.
2. **Short-term Evaluation:** Data was collected over a 2-week period; long-term preference drift is not modeled.
3. **Evaluation Scope:** Testing was limited to simulated users and a closed beta group (N=50), lacking large-scale A/B testing.

6. Research Contribution & Conclusion

- **Unified Contribution Statement:**

This study presents the **first Trilingual Smart Shopping Agent** that integrates **Real-time Cross-Platform Price Normalization** with a **Hybrid AI Recommendation Engine**. Unlike existing systems that focus solely on price or text search, this research contributes a novel **Wastage-Aware Re-ranking Algorithm**, enabling sustainable purchasing decisions in linguistically diverse regions (English, Sinhala, Tamil).

- **Conclusion of Data Analysis**

The project demonstrates that by integrating real-time market data through SerpAPI and advanced reasoning via Gemini AI , we can effectively bridge the gap between fragmented shopping data and personalized sustainability. The results confirm that the "Smart Kitchen Shopping Agent" is technically robust and addresses the core research problem of inefficient and wasteful food purchasing.
